What *exactly* is the CMB telling us?

Although the simplest models of single field inflation remain compatible with current CMB experiments, a direct reconstruction of the primordial power spectrum is still limited by degeneracies in our priors and our systematics:

 The actual raw data from WMAP has been extensively processed- binning in I-space, 'outliers' accorded less significance etc. Features of heavy physics in the CMB

 The quality of data available to us is due to vastly
- improve in the coming years (PLANCK, CMBPol)- we may be able to more accurately constrain (or even detect!) non-trivial non-gaussianities in the CMB (and thus test models containing comsic strings, stringy inflation, alternatives to inflation).

Inflation with a mass hierarchy

In addition to the importance of understanding what the CMB is actually telling us about the primordial power spectrum, we also need to explore what features realistic models of inflation might actually be generating.

In the moments of the CMB, there is in principle a lot of information about the Lagrangian of inflation. The simplest analyses of the currently available data seems to suggest:

In this talk, we wish to discuss inflation in the setting where it is an effective light direction in a multi-dimensional field space (representative of inflation realized in string theory), where we see that:

Heavy physics does not necessarily decouple, and in certain generic situations, can imprint itself on the CMB as superimposed damped oscillatory features (or, truncating is not the same as integrating out).

Our highest energy probe? Probing compactifications?

Inflation with a mass hierarchy

To say that there is effectively one light scalar direction at such potentially high energies, with negligible interactions with other light directions if they exist (to ensure adiabaticity) is a strong statement. Furthermore:

- ▶ The slow roll conditions $\epsilon, \eta \ll 1$ are very difficult to maintain at the quantum level
- Imagine a heavy scalar interacting with the inflaton (as in hybrid inflation):

 $V(\phi, \chi) = V_{inf}(\phi) - \frac{1}{2}m^2\chi^2 + \frac{1}{2}g\chi^2\phi^2$, then the loop corrected potential is given by $V_{eff}(\phi) = V_{inf}(\phi) + V_{ct} + \frac{M^4(\phi)}{64\pi^2} ln[M^2(\phi)/\mu^2]$

To maintain slow roll at the quantum corrected level, we require that the *effective potential* satisfy the slow roll conditions. Features of heavy physics in the CMB

Non decoupling of heavy physics?

So it is the parameters of the effective inflaton action that we require to satisfy the slow roll requirements. It seems that heavy physics can only manifest as irrelevant (Planck suppressed) operators.

However heavy physics does not always decouple so cleanly from low energy physics. There are certain situations in which the conditions underlying the decoupling theorem (Appelquist, Carrazone) may not be met:

Perturbations

We now consider perturbations around a background solution $\phi^a(\tau, x) = \phi^a_0(\tau) + \delta \phi^a(\tau, x)$, with a perturbed line element $ds^2 = a^2(\tau)[-d\tau^2(1+2\psi(\tau, x)) + (1-2\psi(\tau, x))dx^idx^i]$.

Expanding the gravitational and scalar field action to second order, we express perturbations in terms of the (gauge invariant) 'Mukhanov-Sasaki' variables:
y^a = a[5,d^a] + ^{d^a}/₂ a(1) to obtain the equations of motion

 $v^a\equiv a[\delta\phi^a+rac{\phi_{ au}^a}{{\cal H}}\psi]$, to obtain the equations of motion:

Perturbations

We now consider perturbations around a background solution $\phi^a(\tau, x) = \phi^a_0(\tau) + \delta \phi^a(\tau, x)$, with a perturbed line element $ds^{2} = a^{2}(\tau) \left[-d\tau^{2} (1 + 2\psi(\tau, x)) + (1 - 2\psi(\tau, x)) dx^{i} dx^{i} \right].$

Expanding the gravitational and scalar field action to second order, we express perturbations in terms of the (gauge invariant) 'Mukhanov-Sasaki' variables: $v^a \equiv a[\delta \phi^a + \frac{\phi^a_{\tau}}{2 \nu} \psi]$, to obtain the equations of motion:

 $\frac{d^2 v_{\alpha}^T}{d\tau^2} + 2\zeta \frac{dv_{\alpha}^N}{d\tau} - \zeta^2 v_{\alpha}^T + \frac{d\zeta}{d\tau} v_{\alpha}^N + \Omega_{TN} v_{\alpha}^N + (\Omega_{TT} + k^2) v_{\alpha}^T + \frac{\text{Bergs in field space}}{\text{Federes in the power spectrum}} = 0$

Features of heavy physics in the CMB

Perturbations

We now consider perturbations around a background solution $\phi^a(\tau, x) = \phi^a_0(\tau) + \delta \phi^a(\tau, x)$, with a perturbed line element $ds^2 = a^2(\tau)[-d\tau^2(1+2\psi(\tau, x)) + (1-2\psi(\tau, x))dx^idx^i]$.

Expanding the gravitational and scalar field action to second order, we express perturbations in terms of the (gauge invariant) 'Mukhanov-Sasaki' variables:
 v^a ≡ a[δφ^a + φ^a/_Tψ], to obtain the equations of motion:

$$\begin{aligned} &\frac{d^2 v_{\alpha}^T}{d\tau^2} + 2\zeta \frac{d v_{\alpha}^N}{d\tau} - \zeta^2 v_{\alpha}^T + \frac{d \zeta}{d\tau} v_{\alpha}^N + \Omega_{TN} v_{\alpha}^N + (\Omega_{TT} + k^2) v_{\alpha}^T \\ &\frac{d^2 v_{\alpha}^N}{d\tau^2} - 2\zeta \frac{d v_{\alpha}^T}{d\tau} - \zeta^2 v_{\alpha}^N - \frac{d \zeta}{d\tau} v_{\alpha}^T + \Omega_{NT} v_{\alpha}^T + (\Omega_{NN} + k^2) v_{\alpha}^N \end{aligned}$$

$$\blacktriangleright \text{ With } \zeta \equiv Z_{TN} = a H \eta_{\perp} , \\ &\Omega_{TT} = -a^2 H^2 \left(2 + 2\epsilon - 3\eta_{||} + \eta_{||} \xi_{||} - 4\epsilon \eta_{||} + 2\epsilon^2 - \eta_{\perp}^2 \right) , \\ &\Omega_{NN} = -a^2 H^2 (2 - \epsilon) + a^2 M^2 , \\ &\Omega_{TN} = a^2 H^2 \eta_{\perp} (3 + \epsilon - 2\eta_{||} - \xi_{\perp}) \text{ and } \xi_{\perp} \equiv -\frac{\dot{\eta}_{\perp}}{H \eta_{\perp}} . \end{aligned}$$

Numerics

We numerically evaluate the power spectrum from the full coupled equations, and from the effective theory. We evaluate the resulting power spectrum from a single sudden bend in field space preserving slow roll. We pick a fiducial background solution which renders the attractor values $\epsilon = 0.022, \eta_{||} = 0.034$ in the absence of any bending in field space. N.B. in what follows, we have COBE normalized at the pivot scale $k_* = 0.002 Mpc^{-1}$.

As advertised, very prominent oscillatory features present. Could such a primordial spectrum off a better (e.g. χ^2) fit to the data?

 As advertised, effective field theory manifests for the longest wavelengths, a reduced speed of sound.

As advertised, very prominent oscillatory features present. Could such a primordial spectrum off a better (e.g. χ^2) fit to the data?

- As advertised, effective field theory manifests for the longest wavelengths, a reduced speed of sound.
- Thus we expect correlated (equilateral) non-gaussianities
