Robinson-Trautmann spacetimes

- The Robinson-Trautmann (RT) spacetimes are solutions of Einstein equations in d = 4 [I. Robinson and A. Trautman, (1960)]
- They describe the gravitational field due to a compact star which relaxes to equilibrium by radiating away its excess energy and asymmetry.
- In recent times they have been used to model qualitative features of mergers of black holes.

4 **A b b b b b b**

RT spacetimes and SUSY quantum mechanics

- At late times the solution tends to the Schwarzschild solution.
- The leading deviation from Schwarzschild is a very special linearized perturbation of Schwarzschild: the so-called algebraically special mode [Chandrasekhar].
- Perturbations of Schwarzschild are organized according to an underlying supersymmetric quantum mechanics.
- The algebraically special modes are the corresponding supersymmetric ground states (zero energy states).
- The Robinson-Trautman solution is a non-linear version of the algebraically special perturbations of Schwarzschild.

Robinson-Trautmann spacetimes and holography

- The solution exists for any value of the cosmological constant.
- With negative cosmological constant, the solution is a (rare example of a) time-dependent asympotically locally AdS solution.
- At late times, it approaches the AdS-Schwarzschild solution.
- It provides a laboratory for exploring out-of-equilibrium dynamics and the approach to equilibrium using gauge/gravity duality.

Robinson-Trautman spacetimes

The metric is given by

$$ds_{RT}^2 = -Fdu^2 - 2dudr + \frac{r^2}{\sigma^2}d\Sigma_k^2$$

with $d\Sigma_k^2$ a constant curvature metric $(R_k = 2k, k = 0, \pm 1)$.

The function F is uniquely determined in terms of σ ,

$$F \equiv -\frac{\Lambda}{3}r^2 - 2r\frac{\partial_u\sigma}{\sigma} + \frac{R_g}{2} - \frac{2m}{r}$$

where Λ is related to the cosmological constant and R_g is the curvature of $d\Sigma_k^2/\sigma^2.$

• $\sigma(x^a, u)$ should solve the *Robinson-Trautman equation*,

$$12m\partial_u \sigma^2 + 2\sigma^4 \nabla_{\Sigma_k}^2 \sigma^2 + \sigma^4 \nabla_{\Sigma_k}^2 \left(\sigma^2 \nabla_{\Sigma_k}^2 \log \sigma^2\right) = 0.$$

Robinson-Trautman equation and the Calabi flow

 The Robinson-Trautman equation coincides with the Calabi equation,

$$\partial_u g_{ab} = \frac{1}{12m} \nabla_g^2 R_g \, g_{ab}.$$

which describes a class of deformations of the 2d metric

$$ds_2^2 = \frac{1}{\sigma^2} d\Sigma_k^2$$

> The Calabi flow is defined more generally for a metric $g_{a\bar{b}}$ on a Kähler manifold M by the Calabi equation

$$\partial_u g_{a\bar{b}} = \frac{\partial^2 R}{\partial z^a \partial z^{\bar{b}}}$$

where R is the curvature scalar of g.

It provides volume preserving deformations within a given Kähler class of the metric.

Calabi flow on M^2

- The Calabi flow can be regarded as a non-linear diffusion process.
- The steady state solutions are constant curvature metrics (up to conformal transformations).
- For compact M² the flow monotonically deforms the metric to the steady state solution.
- For non-compact M² it seems there is no full classification of the late time behaviour.

AdS Schwarzschild as Robinson-Trautman

> Using the fixed point solution for the case of S^2

$$\frac{1}{\sigma_0^2} = \frac{1}{\left(1 + z\bar{z}/2\right)^2} \,.$$

the metric becomes

$$ds^{2} = \frac{2r^{2}}{\left(1 + z\bar{z}/2\right)^{2}}dzd\bar{z} - 2dudr - \left(1 - \frac{2m}{r} - \frac{\Lambda}{3}r^{2}\right)du^{2}$$

which is the Schwarzschild metric in the Eddington - Finlkenstein coordinates.

Similarly, one obtains the AdS brane brane and the hyperbolic AdS black hole in the other two cases.

RT as an Asymptotically locally AdS solution

When Λ < 0 the solution is asymptotically locally AdS. This means that near the conformal boundary the metric takes the Fefferman-Graham form:

$$ds^{2} = \frac{d\varrho^{2}}{\varrho^{2}} + \frac{1}{\varrho^{2}} \left(g_{(0)ab}(x) + \varrho^{2} g_{(2)ab}(x) + \varrho^{3} g_{(3)ab}(x) + \cdots \right) dx^{a} dx^{b}$$

> One can reach this gauge by a coordinate transformation $(r^* = u - t, t, z, \overline{z}) \rightarrow (\varrho, t, z, \overline{z})$:

Asymptotic structure

The boundary metric is time-dependent and it is not conformally flat

$$ds_0^2 = -dt^2 + \frac{L^2}{\hat{\sigma}^2} d\Sigma_k^2$$

where $\hat{\sigma}(x^a, t) = \sigma(x^a, u = t - r^*)|_{r^*=0}$ and $L^2 = -3/\Lambda$.

➤ $g_{(2)ab} = -\mathcal{R}_{ab} + \frac{1}{4}\mathcal{R}g_{(0)ab}$, where \mathcal{R}_{ab} is the Ricci tensor of $g_{(0)}$, as expected [de Haro, Solodukhin, KS].

Energy-momentum tensor

Asymptotically locally AdS spacetime come equipped with a conserved T_{ab} which in even dimension is traceless,

$$\nabla^b T_{ab} = 0, \qquad T_a^a = 0$$

The tensor can be extracted from the asymptotics of the solution [Henningson, KS][de Haro, Solodukhin, KS]

$$T_{ab} = -\frac{3}{2\kappa^2} \left(-\frac{3}{\Lambda}\right) g_{(3)ab}$$

> For example, for the case of S^2 we obtain,

$$\begin{split} \kappa^2 T_{tt} &= -\frac{2m\Lambda}{3} , \qquad \kappa^2 T_{tz} = -\frac{1}{2} \partial_z (\hat{\Delta} \hat{\Phi}) \\ \kappa^2 T_{z\bar{z}} &= m e^{\hat{\Phi}} , \qquad \kappa^2 T_{zz} = -\frac{3}{4\Lambda} \partial_t \left((\partial_z \hat{\Phi})^2 - 2\partial_z^2 \hat{\Phi} \right), \end{split}$$

where $\hat{\Phi} = -\log \hat{\sigma}$

Study 1 Study 2

Hydrodynamics

- On general grounds, sufficiently close to equilibrium one expects a hydrodynamic description.
- At sufficient late times, the holographic energy momentum tensor of RT spacetimes should take a hydrodynamic form,

$$T^{ab} = \rho u^a u^b + p \Delta^{ab} - \eta \sigma^{ab}$$

... and indeed it does.

Study 1 Study 2

Out of equilibrium

- > Is there always a notion of local energy density?
- How does the system equilibrate?

Study 1 Study 2

Local energy density

> The local energy ϵ is defined as the eigenvalue of the energy momentum tensor corresponding to a timelike eigenvector:

$$T^{\mu}_{\ \nu}u^{\nu} = -\epsilon u^{\mu}$$
 with $u^{\mu}u_{\mu} = -1$

This defines also the local velocity field u^{μ} .

- One can show analytically that for RT solution, a positive local energy exist to all orders in the late time expansion of the bulk metric.
- > What about early times?
- If the non-equilibrium state is sufficiently close to the thermal state, then there exist a local energy density also at early times.
- Otherwise, a local energy density may not exist.

Study 1 Study 2

Kostas Skenderis Out of equilibrium dynamics and Robinson-Trautman spacetimes

Study 1 Study 2

Pressures and strain

If u^{μ} exists, we construct two vectors, $n_{I}^{\mu}(I=1,2)$,

$$n_I \cdot n_J = \delta_{IJ} \qquad u \cdot n_I = 0,$$

and use them to define two pressures and the strain

$$p_1 = n_1 \cdot T \cdot n_1 \qquad p_2 = n_2 \cdot T \cdot n_2, \qquad t = n_1 \cdot T \cdot n_2$$

For axially symmetric solutions t = 0.

Study 1 Study 2

Approach to equilibrium

> 'Hydrodynamisation' time, t_{hyd} :

$$\max_{x} \left| \frac{p_{I} - p_{I}^{(1)}}{\bar{p}} \right| < \frac{1}{10}, \qquad (t_{hyd})$$

> Energy equilibration time, t_{energy} :

$$\max_{x} \left| \frac{\epsilon - \epsilon_{eq}}{\epsilon} \right| < \frac{1}{10}. \qquad (t_{energy})$$

> Isotropisation time, t_{iso} ,

$$\max_{x} \left| \frac{p_1 - p_2}{\bar{p}} \right| < \frac{1}{10}.$$
 (*t*_{iso})

Study 1 Study 2

> Suppose that we have two semi-infinite rods, each at different temperature T_{\pm} and we join them at t = 0.

How does this system will evolve?

Study 1 Study 2

Conventional material

In conventional materials the evolution will be governed by the heat equation,

$$\frac{\partial f}{\partial t} = D \frac{\partial^2 f}{\partial x^2}.$$

- > This equation is invariant under the scaling, $x \to \lambda^2 x, t \to \lambda t$.
- > There is a self-similar solution $h(\mu(t, x))$, where $\mu = x/t^{1/2}$,

$$h = a + b \operatorname{Erf}\left(\frac{\mu}{2\sqrt{D}}\right)$$

(a, b are integration constants), which is a late-time attractor.

Study 1 Study 2

Strongly interacting systems

- The RT solution can be used to study the same problem for strongly interacting system via gauge/gravity duality.
- > We will work with RT solution on R^2 , with coordinates x, y.
- > We impose translational invariance in y.
- > We impose that the RT solution tends to the AdS black branes with different temperatures, T_{\pm} , as we go to $x \to \pm \infty$ in the other direction.

Study 1 Study 2

Scaling solutions

The RT metric is invariant under the following scaling

$$\begin{array}{rcl} u & \to & \lambda_u u, & x \to \lambda_x x, & y \to \lambda_x y \\ r & \to & \lambda_u^{-1} r, & m \to \lambda_u^{-3} m, & \sigma \to \lambda_x \lambda_u^{-1} \sigma. \end{array}$$

> There is a scaling solution $h(\mu(x,t))$, where $\mu(t,x) = x/t^{1/4}$.

Study 1 Study 2

Attractor behaviour: general initial conditions

Evolution of the initial data showing convergence to the planar similarity solution in red. Each curve shows a different time in the evolution.

Study 1 Study 2

Comments

- We holographically engineered 2+1 dimensional systems which at *t* = 0 are described by two different thermal states infinitely separated in one direction.
- The final state is a self-similar solution which only depends on the left and right temperatures and not on the details of the initial conditions.
- The self-similar solutions are Lifshitz invariant and perturbations around them are governed by the spectrum of operators of an underlying Lifshitz critical theory.
- Our discussion should thus be applicable to all systems which are in the same universality class with this critical point.

 Study 2

5 Conclusions

Conclusions

- The Robinson-Trautman solution is an interesting laboratory to study out-of-equilibrium dynamics.
- We discussed two studies:
 - existence of local rest frame and approach to equilibrium
 heat transport
- > These solutions exhibit many other interesting properties:
 - One can formulate and prove a Penrose inequality and a version of the hoop conjecture [Bakas, KS].
 - 2 They represent the only example, where a 3d geometric flow is embedded in 4d Einstein gravity.
 - 3
